

Multi-Levelled Hierarchical Control to Optimize Workload of a Service- Oriented Platform

Maksim Khegai, Tatiana Kharchenko, Dmitrii Zubok and Alexandr
Maiatin
ITMO University, St.Petersburg, Russia

Table of Contents

- Introduction and motivation
- Basic architecture of the system
- Architecture of the system
- The algorithm
- Experiments results
- Conclusion

Introduction and motivation

- A performance control was and will be a very important part of every computing system
- Modern cloud systems utilize complex system architecture and as a result have a lot of parameters for performance control
- Simultaneous use of several optimization techniques is not widely researched

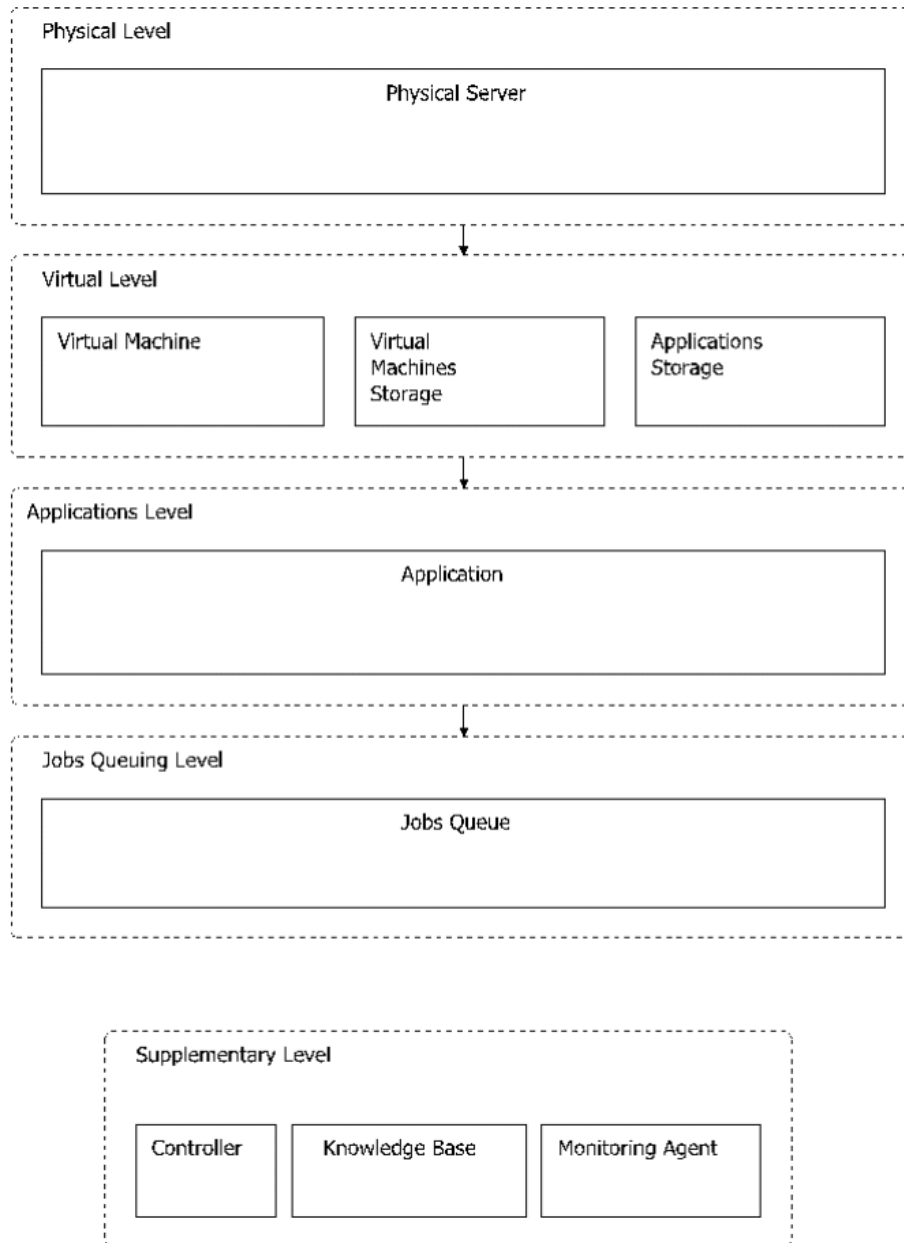

Basic architecture of the system:

Levels

- Physical level
- Virtual level
- Applications level
- Jobs queuing level
- Supplementary level

Basic architecture of the system:

Controller

- Receive a job
- Decide on which path a job must take
- Send data to application
- Receive data from application
- Send a result to user

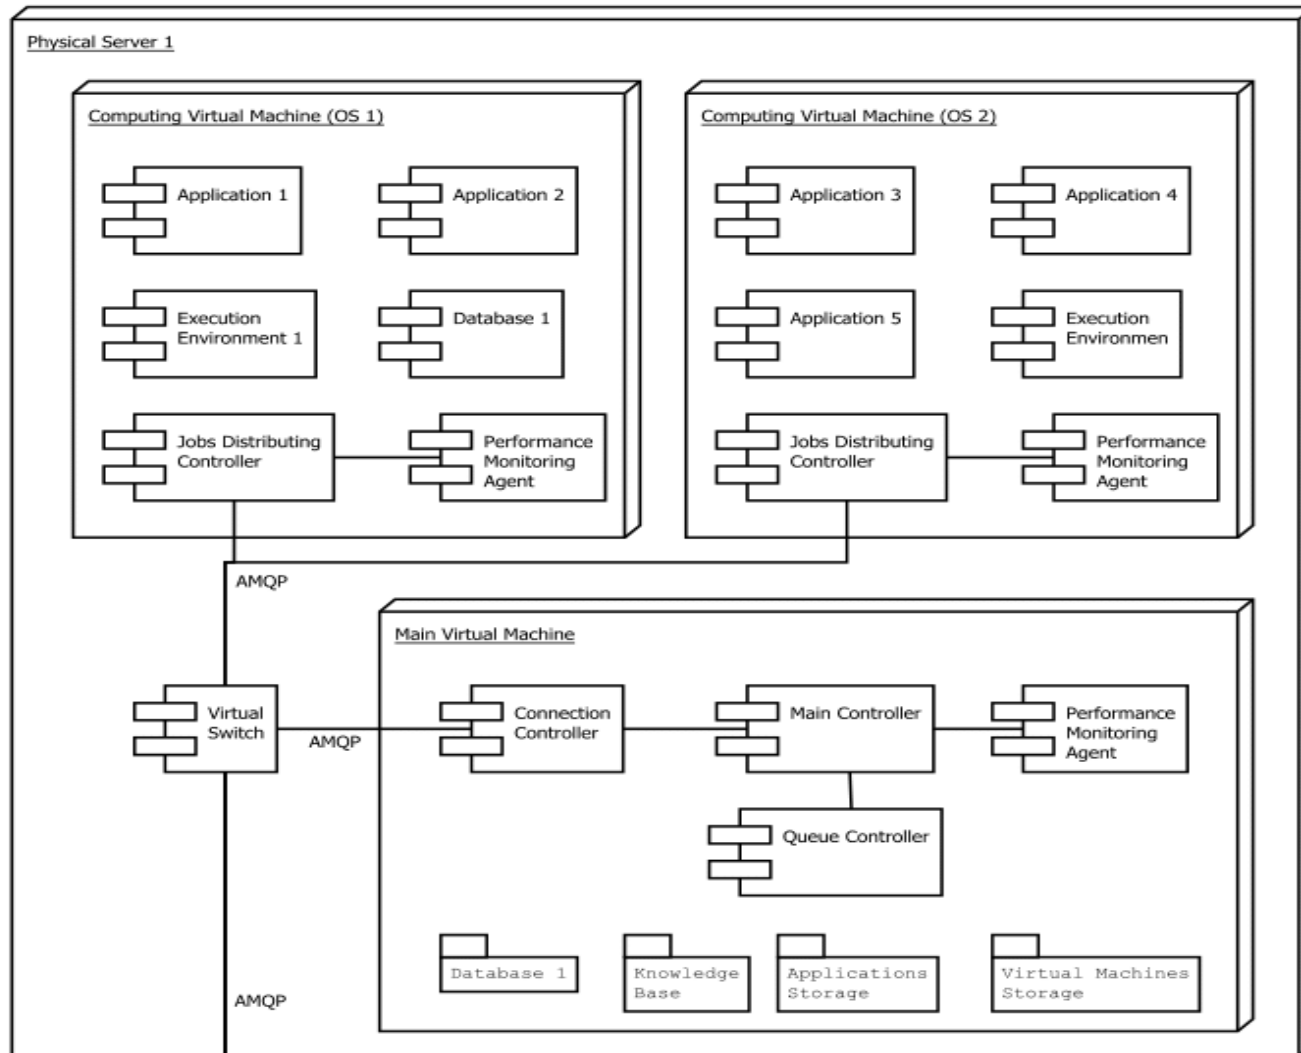

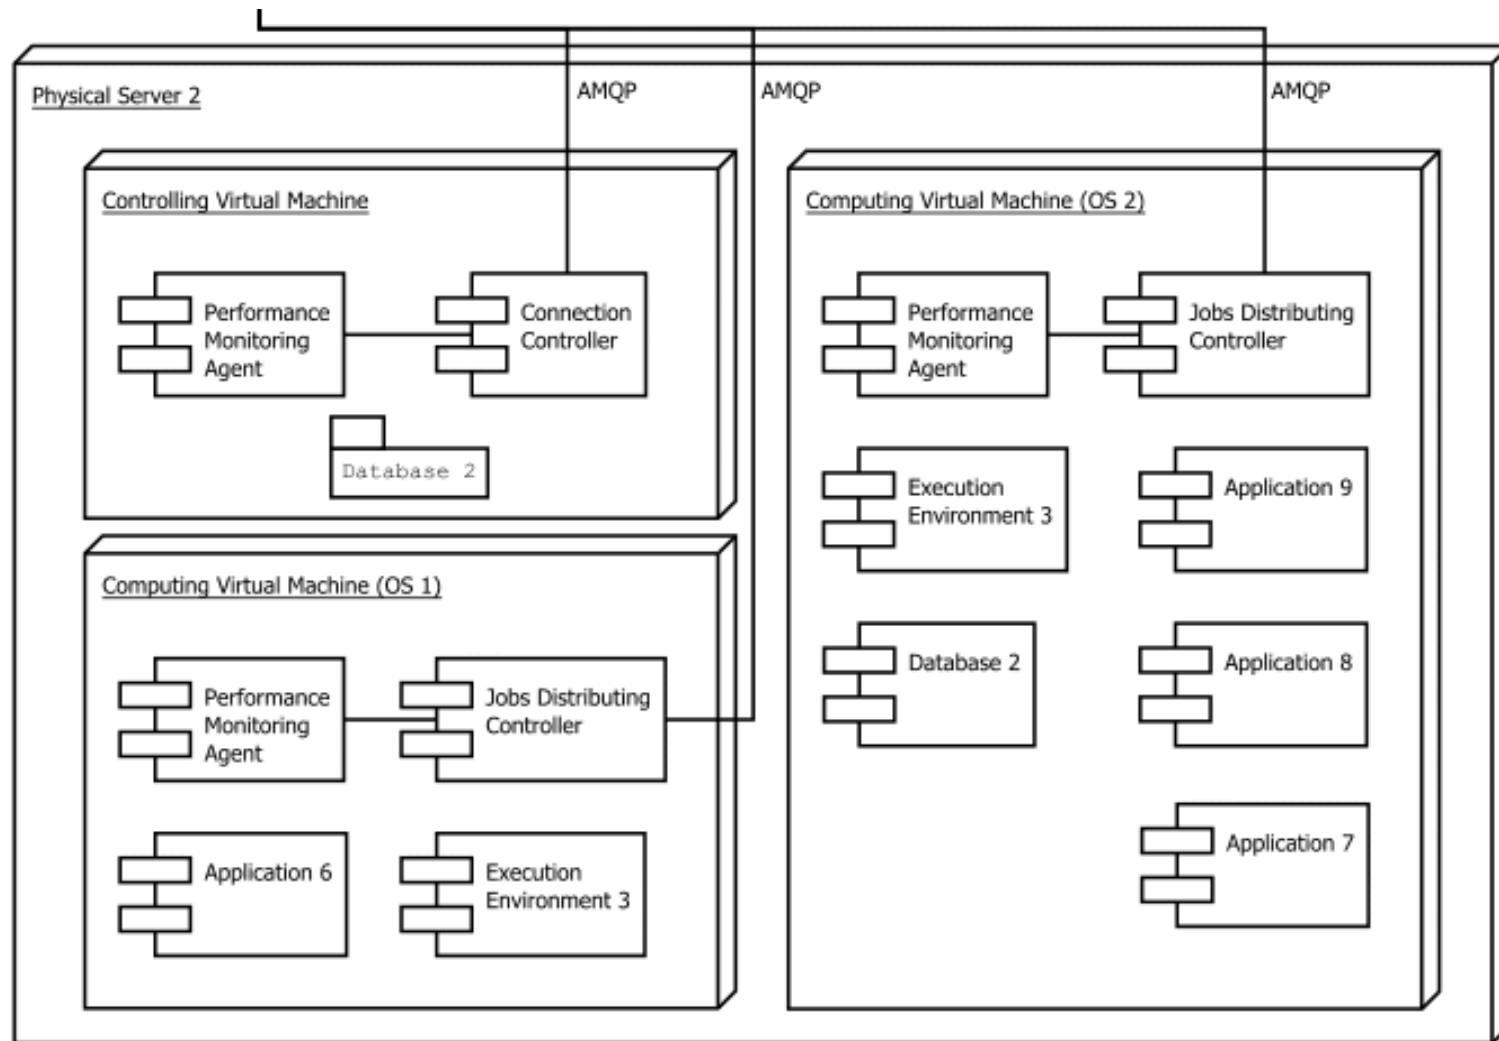

Basic architecture of the system: Optimization

- Monitor performance and available resources
- Search for a path
- Store knowledge about performance for future use

Architecture of the system

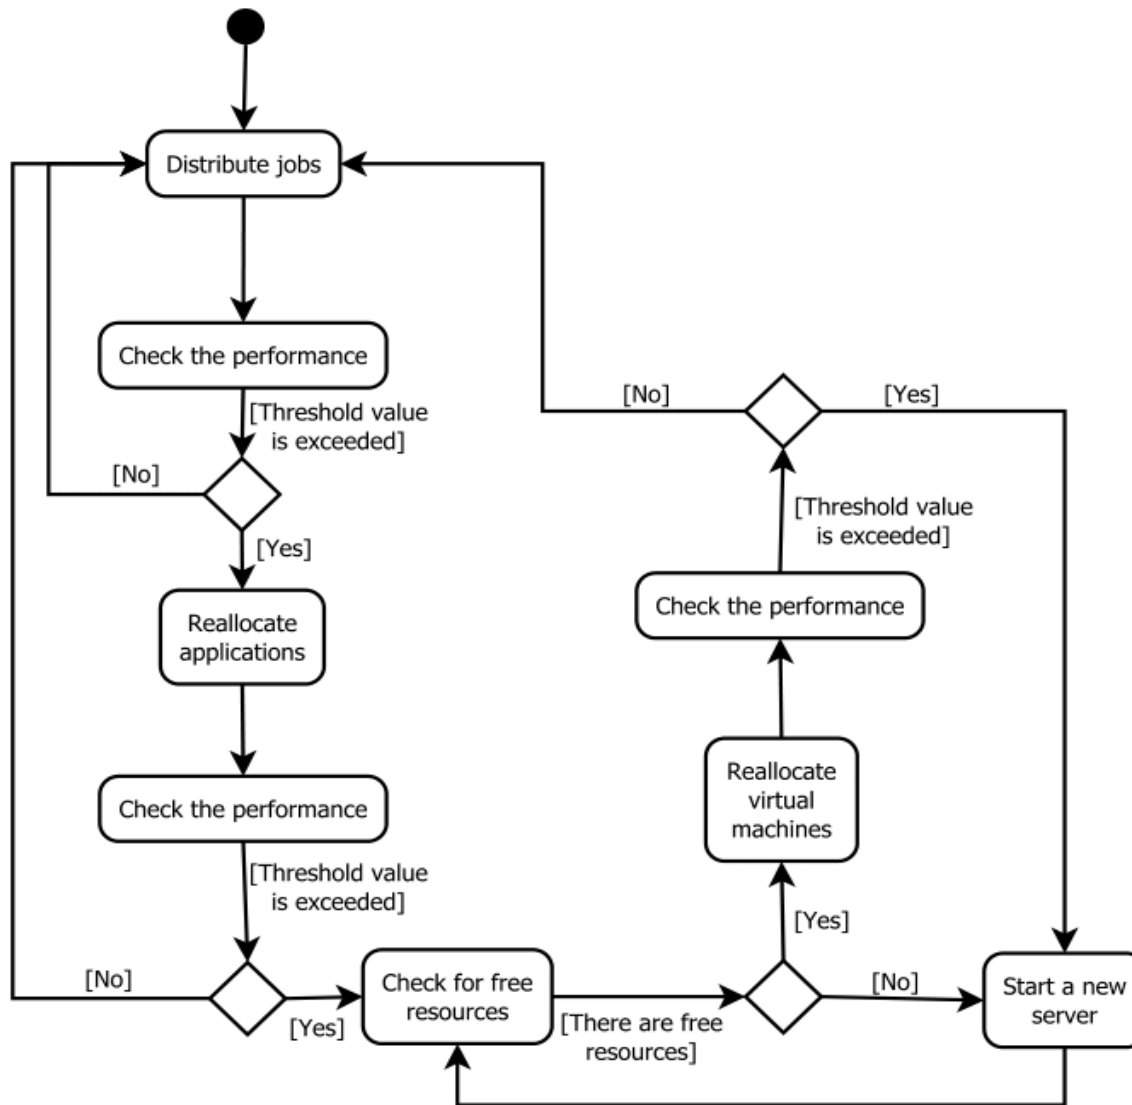

The algorithm

- Jobs queuing step
- Applications redistributing step
- Determine application with lowest performance
- Determine virtual machine with highest performance and maximum free resources
- Check if there are enough resources
- Reallocate application
- Migration and creation of virtual machines
- Starting or stopping physical servers

Experiments results: First step only

Experiments results: Second step only

Experiments results: First and Second steps together

Conclusion

- The performance of the system was improved by using two optimization methods.
- Use of a multi-leveled optimization shows its potential.
- Future work lies in implementing two last steps.

Thank you for your attention
